

Introduction to CCD Astronomy

Jon Rees
Observational Astronomy Workshop

Astronomy By Eye

- Unaided limiting magnitude ~6
- Telescopes brought step-change
- But no direct record of observations, still limited on faint objects, optical illusions

Drawing of Jupiter by James Keeler, 1890 (Credit: Lick Observatory Historical Collections)

Astronomy By Eye

- Unaided limiting magnitude ~6
- Telescopes brought step-change
- But still difficult to deal with faint objects, optical illusions

Drawing of 'canals' on Mars by Percival Lowell, 1905 (Credit: Lowell Observatory)

Linearity

- If detector was perfect, double number of photons -> double counts
- Only true up to a certain count limit
- At high counts, detectors may become non-linear

Saturation

- When electrons reach limit of ADC, no more can be counted
- Bright objects can cause electrons to exceed full well depth pixels
- Electrons will start to fill neighbouring pixels causing bleed trails

Electron bleed trails from saturated stars (Credit:ESO)

Read Noise

- Conversion from analog to digital signal introduces noise
- Electronics also introduce spurious electrons throughout readout
- Can often decrease read noise by using slower read out modes

Thermal Noise/Dark Current

- Thermal energy can liberate electrons
- These are indistinguishable from electrons liberated by photons
- Solution - cool the detector. Generally use liquid nitrogen
- Dark current negligible at these temperatures

Calibration Files

Bias

- Zero second exposure
- But signal isn't zero?
- We apply a constant voltage to the detector
- Positive base signal - prevent negative values
- Overscan vs Bias frame

Flat-Field

- Uniform illumination source
- Dome flats (easy) vs twilight sky flats (better)
- Shows non-uniformity of detector, along with e.g. dust, filter imperfections

Flat-Field

- Uniform illumination source
- Dome flats (easy) vs twilight sky flats (better)
- Shows non-uniformity of detector, along with e.g. dust, filter imperfections

Flat-Field

- Uniform illumination source
- Dome flats (easy) vs twilight sky flats (better)
- Shows non-uniformity of detector, along with e.g. dust, filter imperfections

Fringing

- Interference due to photons reflecting within CCD
- Occurs longwards of $\sim 700\text{nm}$
- Largely due to atmospheric OH - cannot correct with flats
- But largely stable with time - can use library frames to correct

Example Z-band fringe frame for INTWFC

Cosmic Rays

- Blue - Relatively few events
- Red - Thicker chip, many cosmic ray events

Spectroscopy

- Same ideas apply to spectroscopy
- Bias/Flat fields
- Also arc lamps - wavelength calibration

Arcs

Conclusions

- CCDs are great!
- CCDs are not perfect
- Beware of non-linearity/saturation
- Remember calibration files

Conclusions

- Calibration Files:
 - Bias (Bias Voltage)
 - Flat Field (Non-uniform response)
 - Arcs (Wavelength Calibration)
 - Fringe Frame, Standard Star
